

# Climate imperils Ethiopia's coffee output: study

PARIS, France - Climate change could wipe out more than half of Ethiopia's coffee production unless farmers move to higher ground, scientists warned on Monday. Climbing temperatures and dwindling rainfall have already degraded prime growing areas, such as the Zege Peninsula, they reported in the journal *Nature Plants*.

If global warming continues unabated, up to 60 percent of land currently used to grow coffee beans will be unsuitable for production by the last three decades of the century.

"A 'business-as-usual' approach could be disastrous for the Ethiopia coffee economy in the long-term," said Justin Moat, a professor at the University of Nottingham and lead author of the study.

## Silver lining

But the new research uncovered a silver lining: a timely and well-planned transition to other regions could not only save the country's largest source of export revenue, it could quadruple land under cultivation, the researchers found.

Home of the prized *Coffea arabica* plant, Ethiopia is the world's fifth-biggest producer of beans, after Brazil, Vietnam, Colombia, and Indonesia, according to the International Coffee Organization. The sector employs some 15 million people and accounts for a quarter of the east African nation's foreign earnings, around \$800m (715 million euros) annually.

## Coffee areas in decline

Over the last 50 years, however, average temperatures across the country have risen by about 1.5 degrees Celsius (2.7 degrees Fahrenheit), and rainfall in key regions has become spotty. Coffee areas that once flourished are in decline, dozens of farmers told the researchers over the course of a three-year investigation.

"All but a few reported that there had been changes in their local and regional climate, including an increase in unpredictability of the seasons," co-author Aaron Davis, a scientist at the Royal Botanic Gardens in Surrey, England, told AFP. Over decades, the farmers had also seen less rain, combined with a longer and more intense dry season.

The oldest among them remembered good harvests every year six or seven decades ago, and every three years toward the end of the 20th century, said Davis. Today, bountiful harvests in some key areas happen only once every five years. One of the country's best-known coffee regions, Harar, is likely to disappear before the end of the century, the study forecast.

## **Keeping pace with climate change**

The study calculates that coffee production must move up in elevation some 32 metres per decade "to keep pace with climate change." Currently, coffee is grown between 1,200 and 2,200 metres (4,000 and 7,200 feet).

Climate models projecting changes driven by global warming across all 16 of Ethiopia's coffee growing regions matched the historical data, bolstering confidence in their accuracy.

Fortunately, the potential to migrate coffee farms to higher ground exists. Even if much of the nearly 19,000 square kilometres (7,300 square miles) currently under cultivation becomes marginal, there is more than twice as much suitable land - much of it forested - that could take its place. "It is going to be a massive undertaking - there is time to make the necessary transitions if we start now," said Davis. "But if we wait, it will only become more difficult and more traumatic."
